

MEGAQUAGGA

VULNERABILITY ASSESSMENT

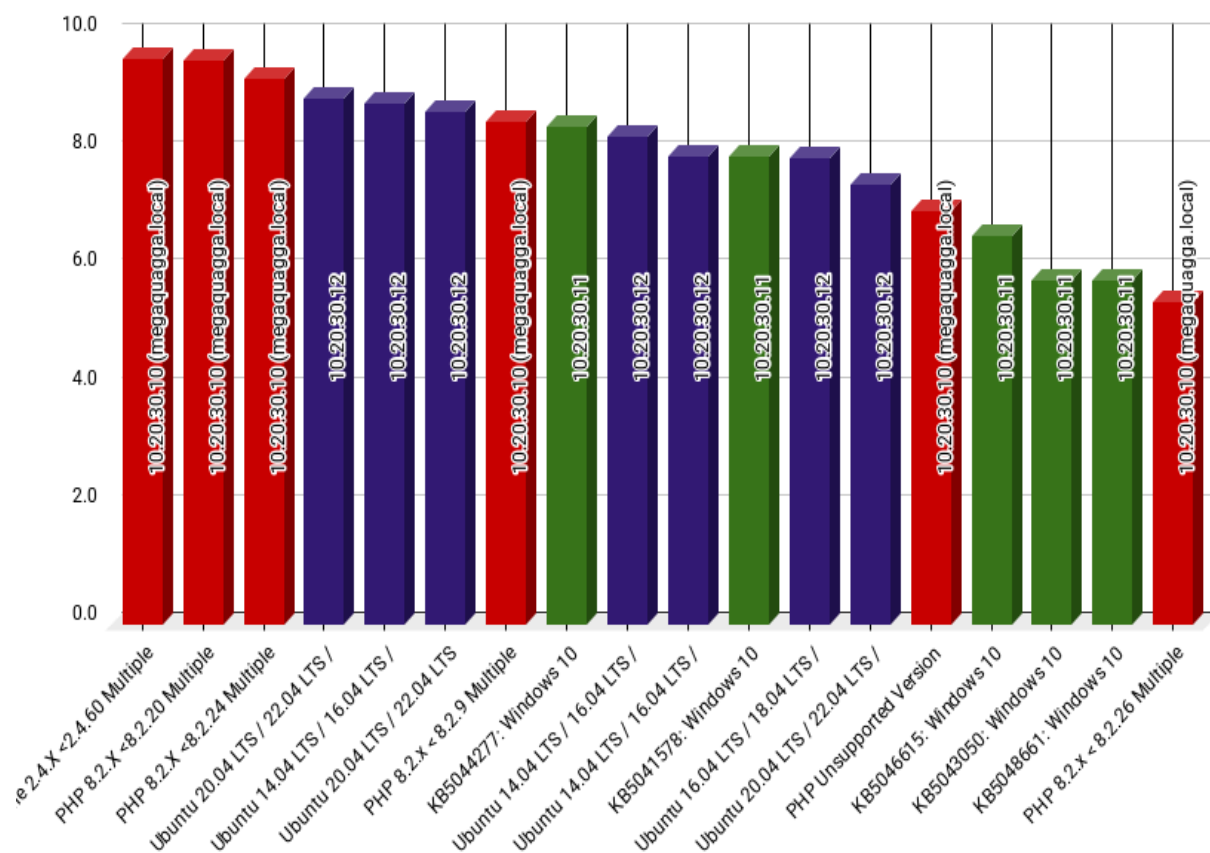

Performed by Jeremy Grantham between 2025-27-10 and 2025-31-10 on behalf of 0x2A Security.

Executive Summary

Vulnerabilities by Asset

Top Vulnerabilities

Based on a review of MegaQuagga's network, eighteen critical vulnerabilities have been identified across three hosts. These vulnerabilities, ranging from low to high severity, require immediate attention. The majority can be resolved by updating outdated software.

The hosts are prioritized for remediation based on the number and severity of critical vulnerabilities found. Host 10.20.30.10 (megaguagga.local), with six vulnerabilities, including three of the most critical, should be addressed first. Host 10.20.30.12 has seven vulnerabilities and should be remediated next, followed by host 10.20.30.11, which has five of the least critical vulnerabilities.

These unpatched systems pose a significant risk of various attacks, which could lead to financial and reputational damage. To mitigate these risks, it is strongly recommended that the following updates be performed:

On host 10.20.30.10: Update Apache to version 2.4.60+ and PHP to version 8.26+.

On host 10.20.30.12: Update all Ubuntu packages to their latest versions.

On host 10.20.30.11: Install security update 5046615.
